# *The evolving Web scenario*

- ◆ Heterogeneous clients
  - ◆ Different display, CPU, network
- ◆ Heterogeneous user behavior
  - ◆ Request for sophisticated, personalized services

**Content adaptation**  
*(transcoding, personalization)*

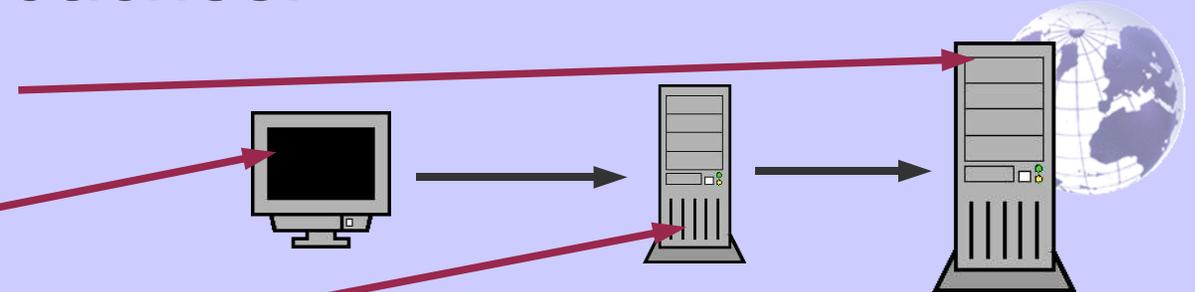

# Content adaptation

- ◆ Possible approaches:

- ◆ Server-based

- ◆ Client-based

- ◆ Intermediary-based

- ◆ Issue:

- ◆ Content adaptation is computationally expensive

- ◆ Typical solutions

- ◆ **Caching** → reduce adaptation operations

- ◆ **Replication** → load sharing

# *Issues for efficient content adaptation*

- ◆ Caching issue
  - ◆ multiple version of every resource → working set size grows
  - ◆ locality improves caching effectiveness
- ◆ Replication issue
  - ◆ provide adequate load sharing

## Contribution:

We propose a novel architecture for distributed content adaptation that **preserves locality** and **provides load sharing**

# *Functions in content adaptation*

## ◆ Main functions:

◆ Gateway → G

◆ Location

◆ Adaptation

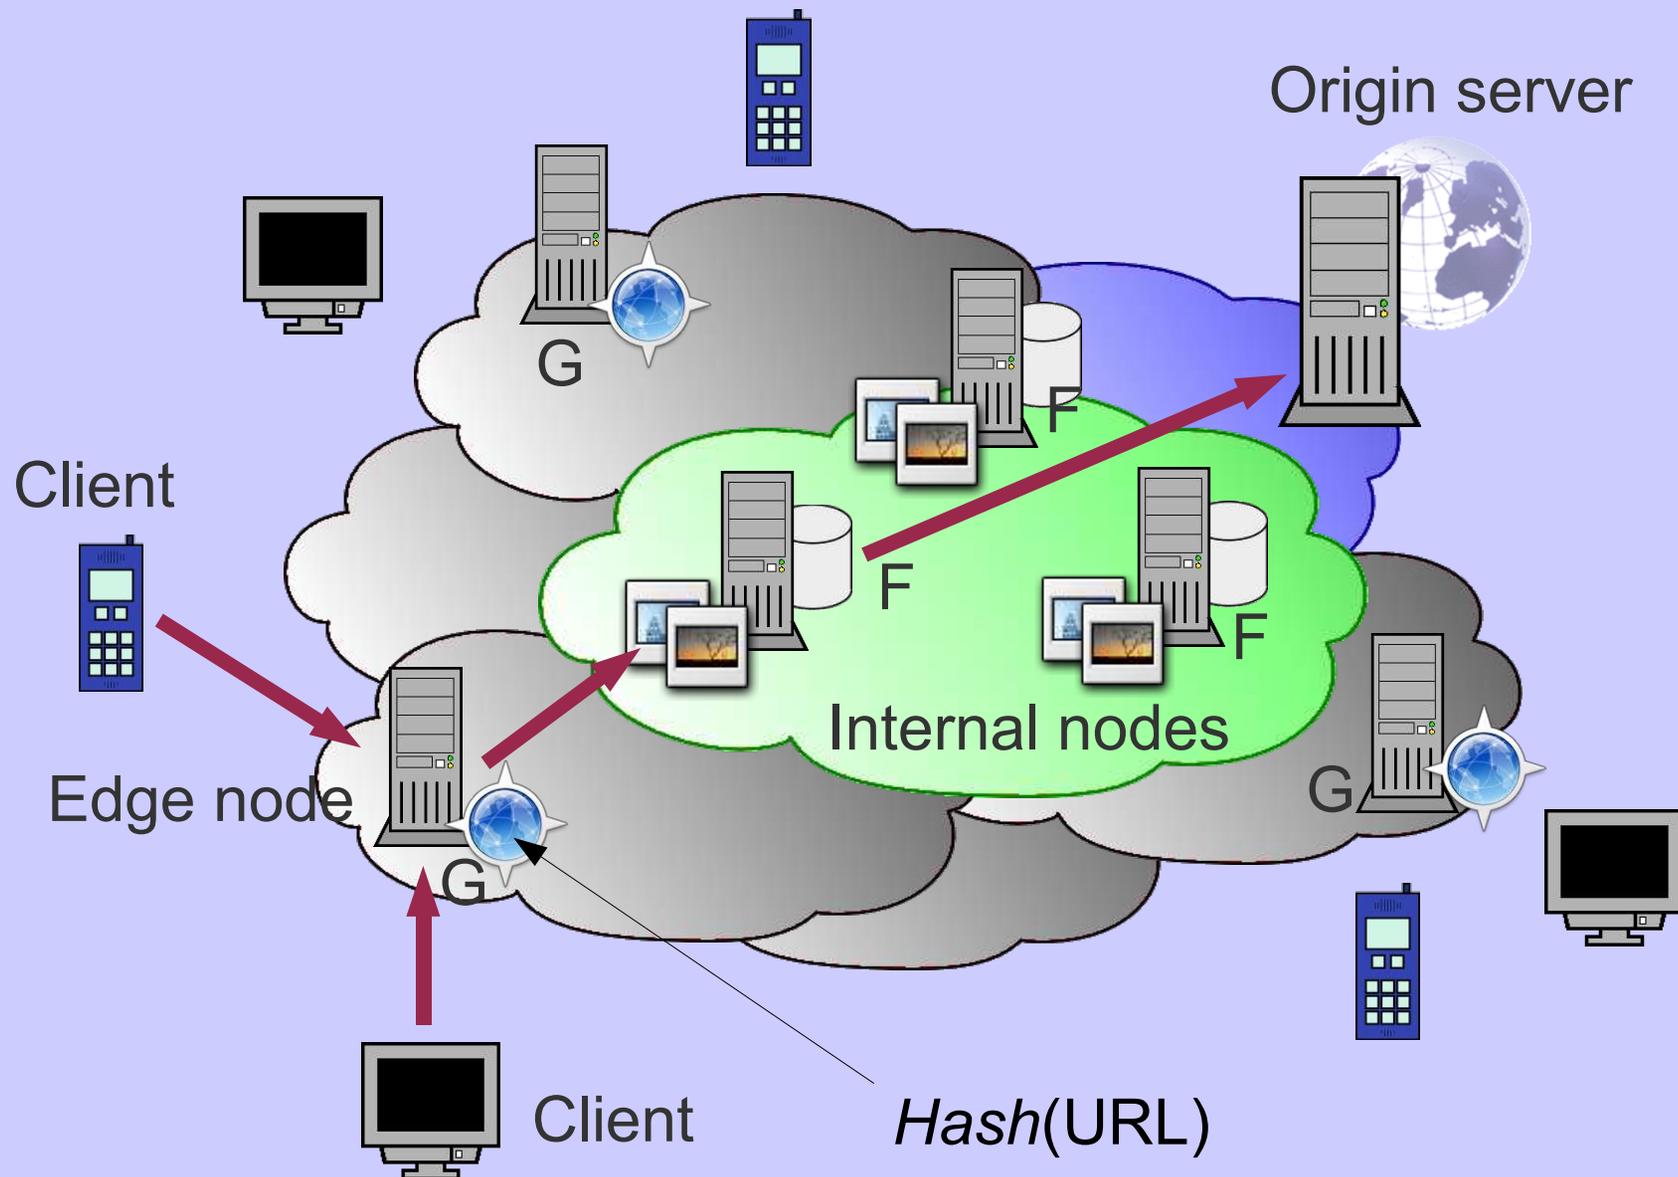

◆ Fetch → F

◆ Cache

Architectures differ in the **mapping** of these functions

# Two-level content adaptation architecture

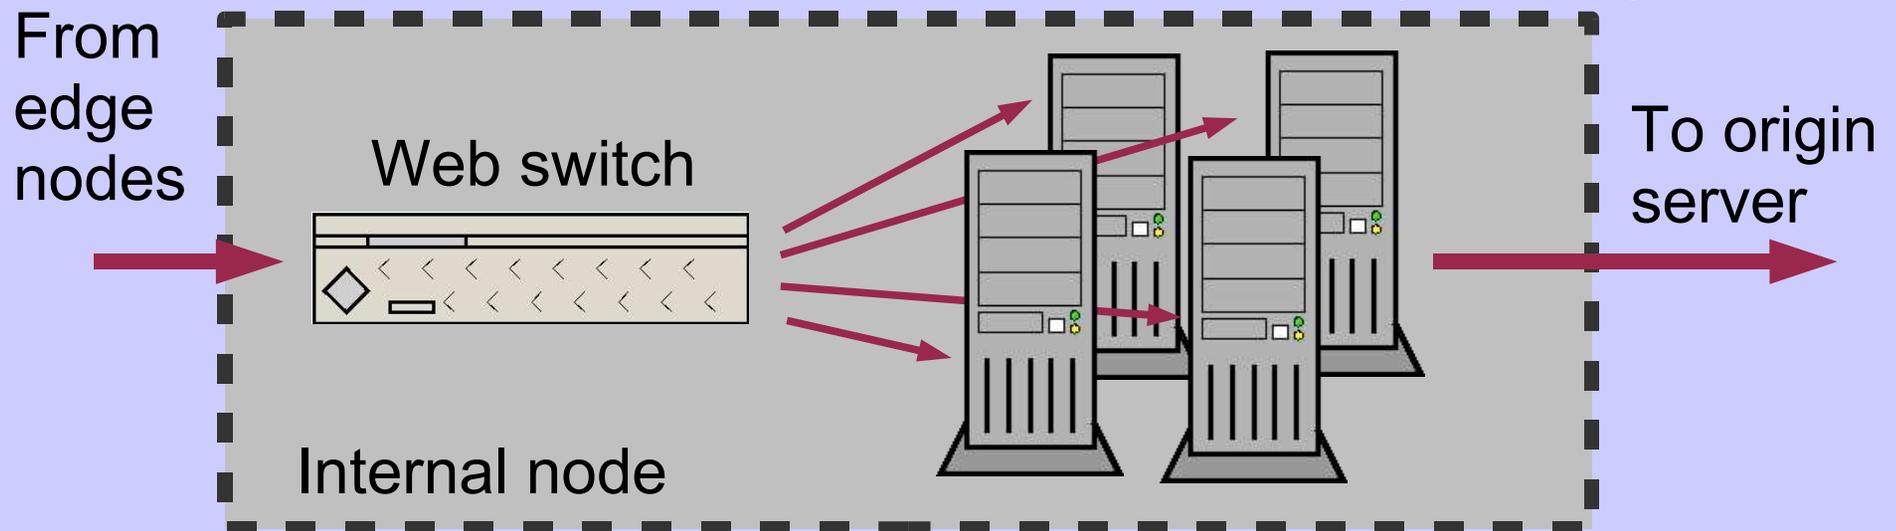

# *Benefit of hashing*

- ◆ Hash computed **only on URL** (no version)
  - ◆ every version of the same resource is on the same node (simplify lookup)
  - ◆ improve **locality**
- ◆ URL-space **partitioned**
  - ◆ no cache duplicates (**efficient use of cache**)
- ◆ Hash-based request distribution
  - ◆ evenly distributed requests (**load sharing**)

# *Two-level content adaptation architecture*

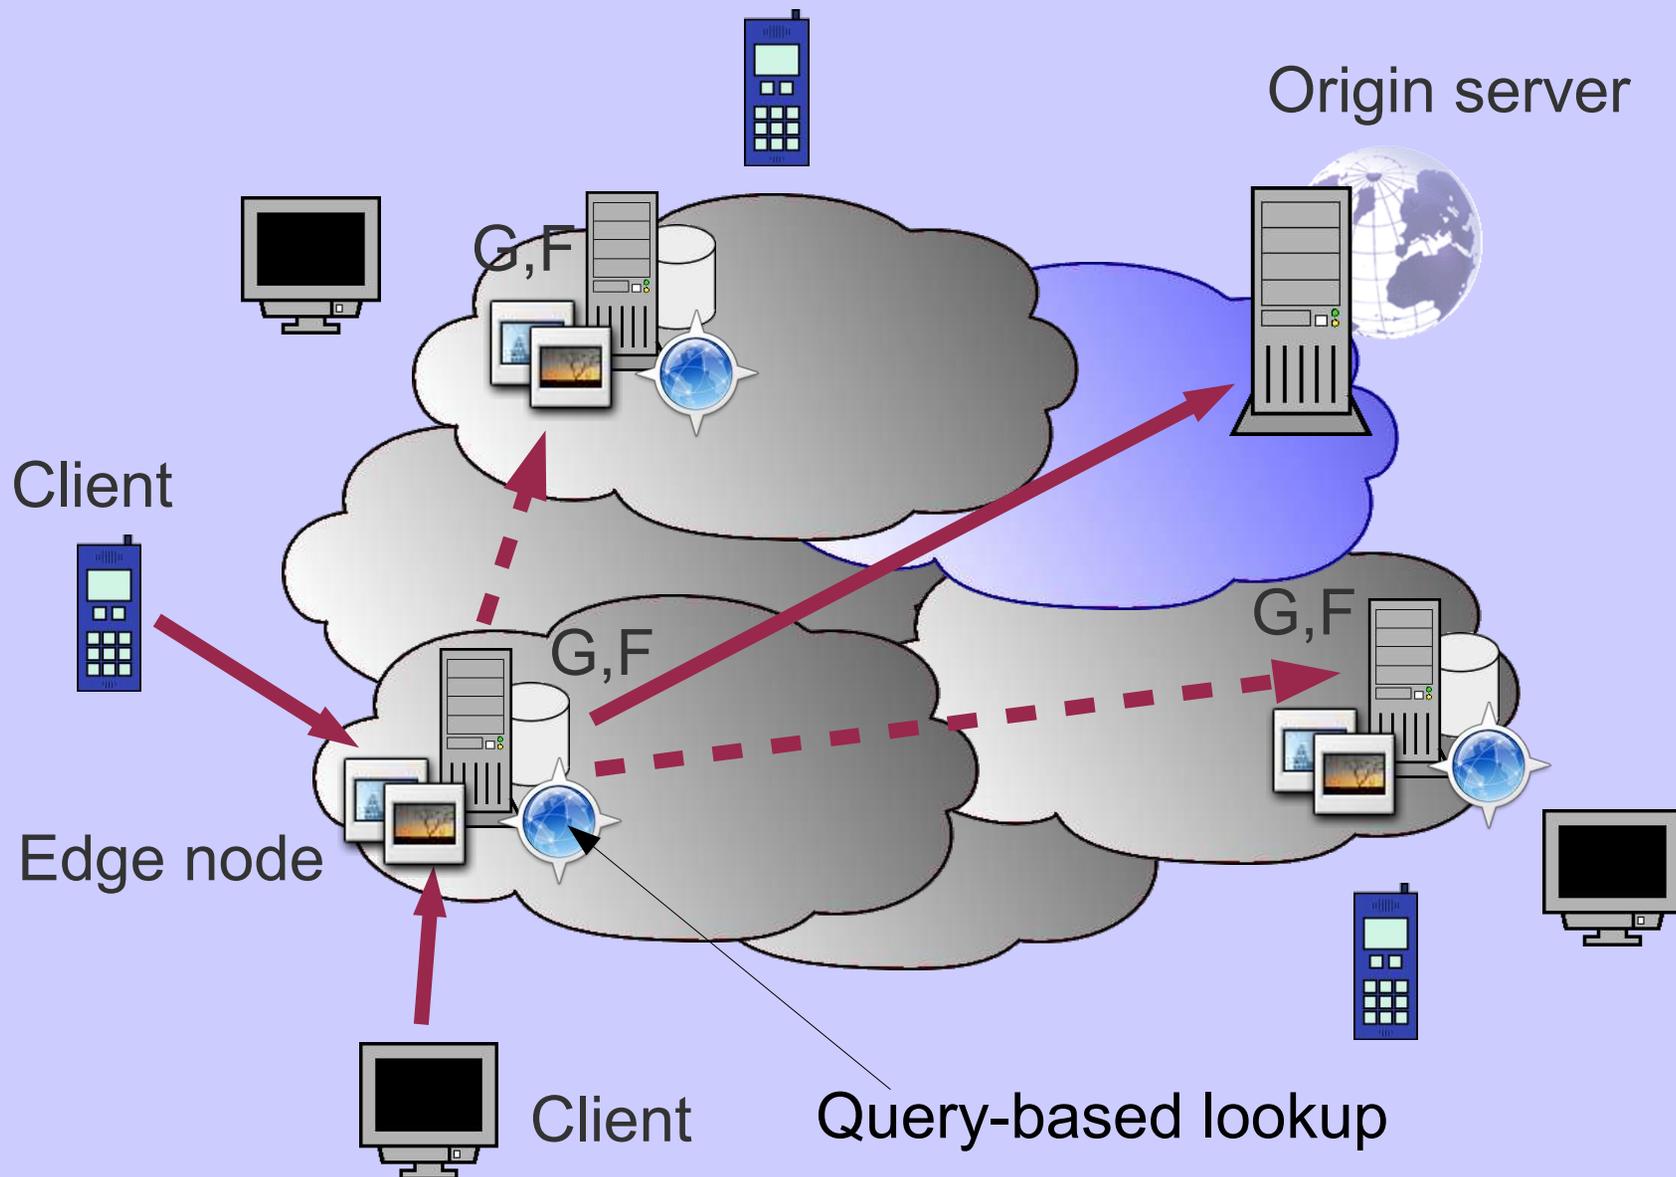

- ◆ Few **powerful internal nodes**:
  - ◆ Improves **security** (easy to control)
  - ◆ Improves **privacy** (sensitive information)
  - ◆ Solves **management** issues (few nodes)
  - ◆ Solves data **consistency** issues (hashing)
  - ◆ Internal nodes can be **locally replicated** to further increase computational power (cluster)

# *Two-level content adaptation architecture*

- ◆ Many **simple** *edge nodes*
  - ◆ no **management** required
  - ◆ no computational **power** required
  - ◆ can be highly **distributed**
  
- ◆ **Drawback** of having two levels
  - ◆ Two steps for every request
  - ◆ We compare the two-level architecture with a *flat architecture*

# *Flat content adaptation architecture*

# *Flat content adaptation architecture*

- ◆ Pros:

- ◆ Highly distributed
- ◆ No need for two steps

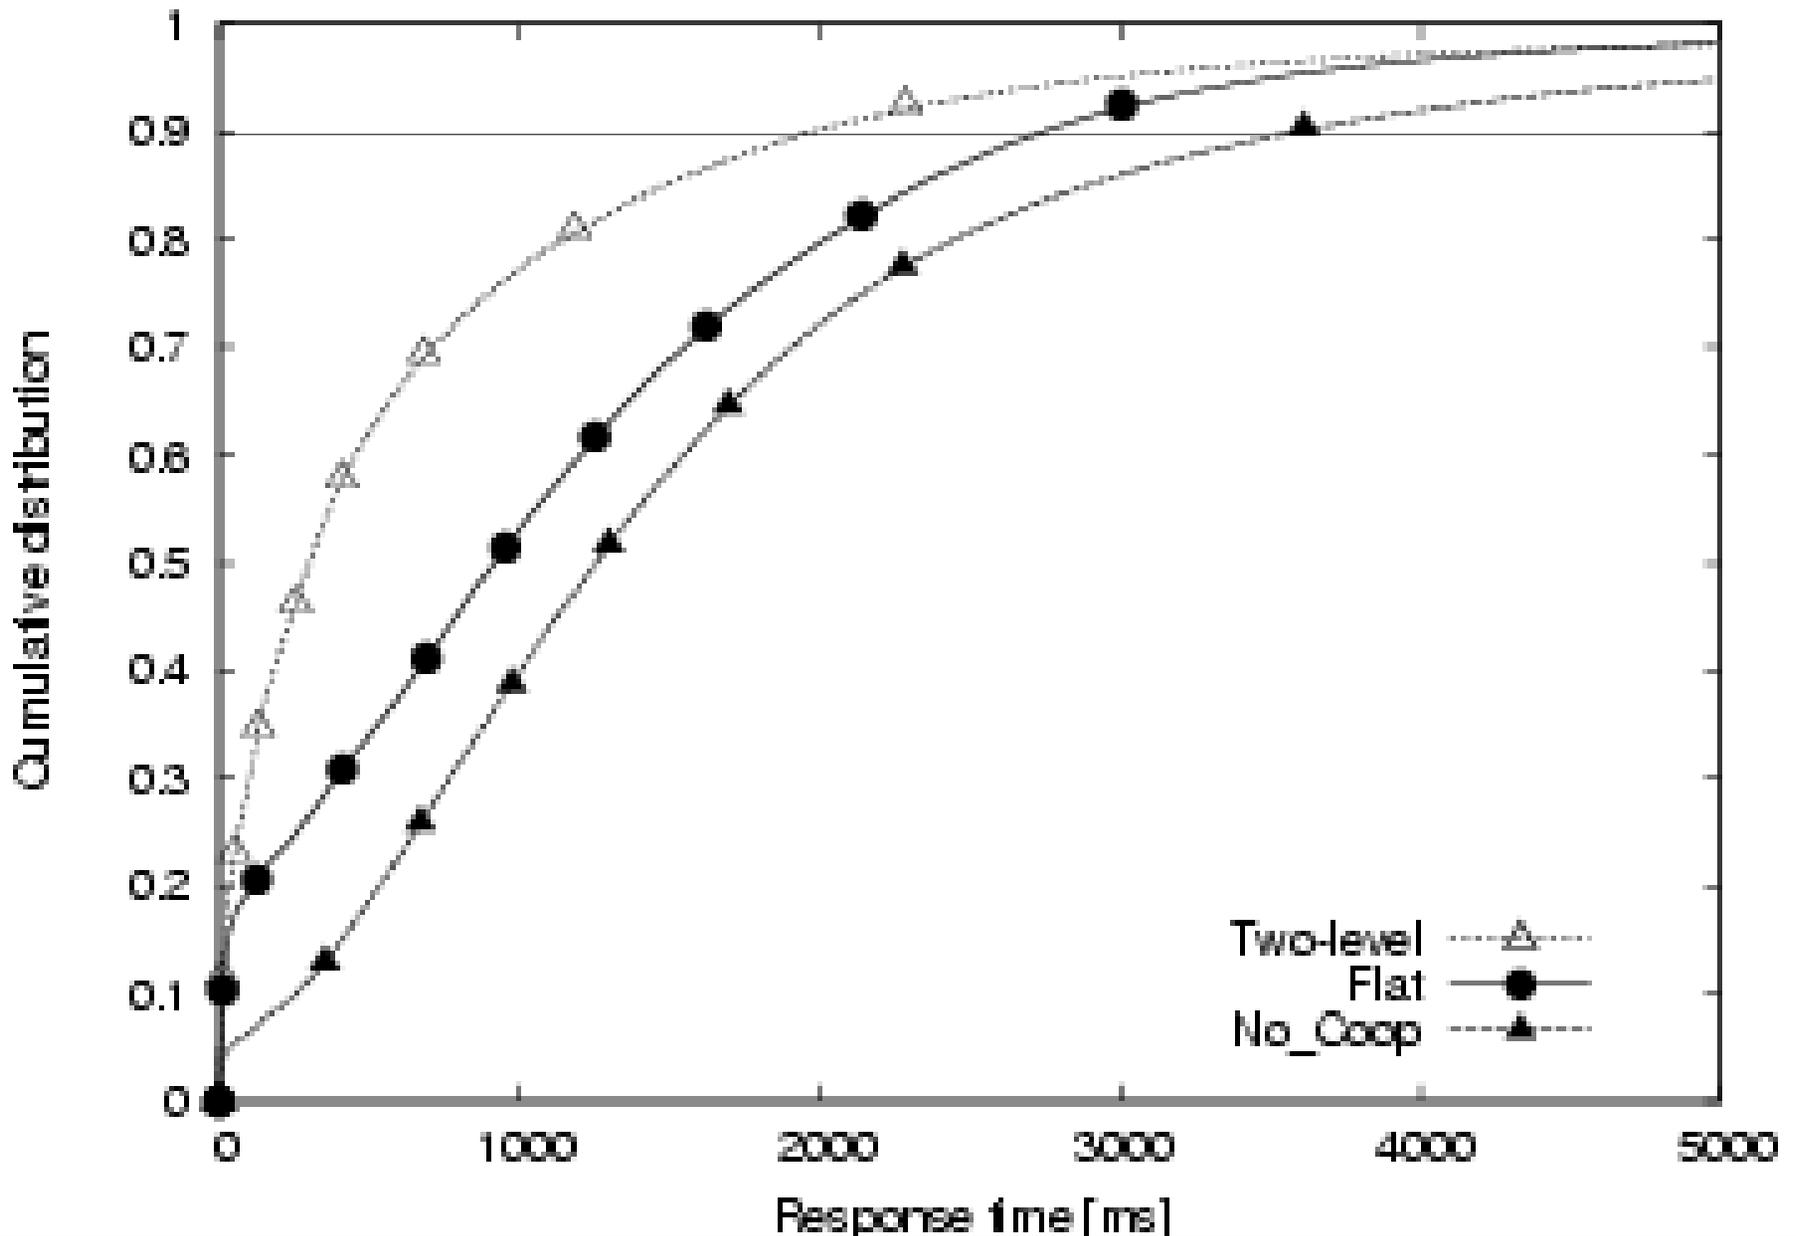

- ◆ Cons:

- ◆ Privacy issues
- ◆ Data consistency issues
- ◆ Does not guarantee load sharing

# *Performance evaluation*

- ◆ Workload models:
  - ◆ Working set with heavy impact on adaptation
  - ◆ Synthetically generated traces
- ◆ We compare:
  - ◆ **Two-level** architecture
  - ◆ **Flat** architecture
  - ◆ **No cooperation** architecture
- ◆ Two network scenario:
  - ◆ Real network scenario
  - ◆ WAN-emulated scenario

# *Real network scenario*

# Hit rate

	local		remote		global
	exact	useful	exact	useful	
<b>No_Coop</b>	8.3%	6.4%	n/a	n/a	14.7%
<b>Flat</b>	8.0%	7.0%	25.1%	26.8%	66.9%
<b>Two-level</b>	n/a	n/a	60.2%	21.0%	<b>81.2%</b>

- ◆ Two-level provides the highest hit rate
- ◆ Hash-based partition is effective in optimizing cache usage

# *Summary of findings*

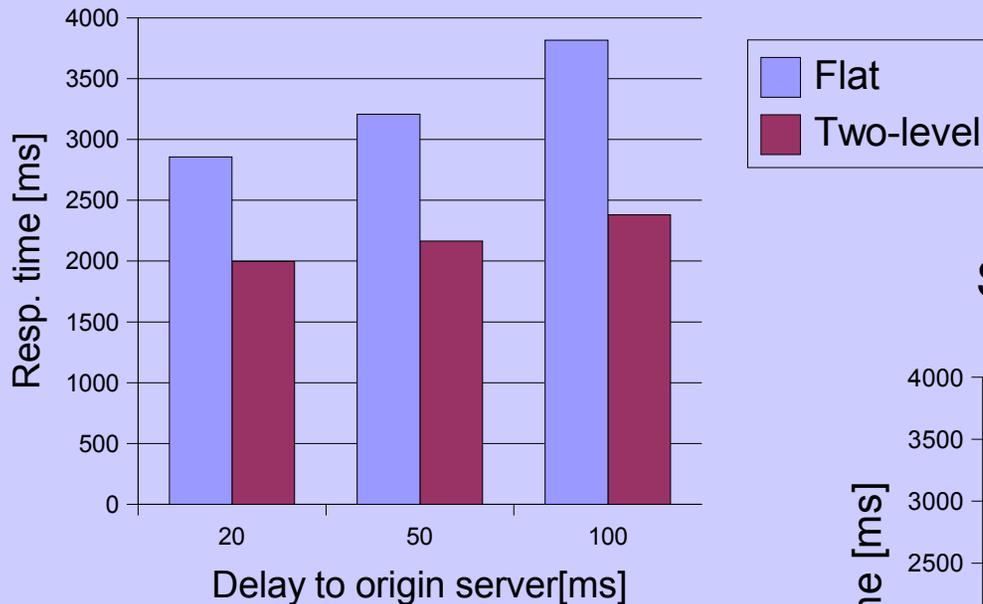

- ◆ Two-level architecture:
  - ◆ Hashing avoids duplicates → efficient cache space usage, high hit rate
  - ◆ High cache hit rate → load is reduced
- ◆ Focus on two-step penalty: sensitivity to network

# *Two-step penalty*

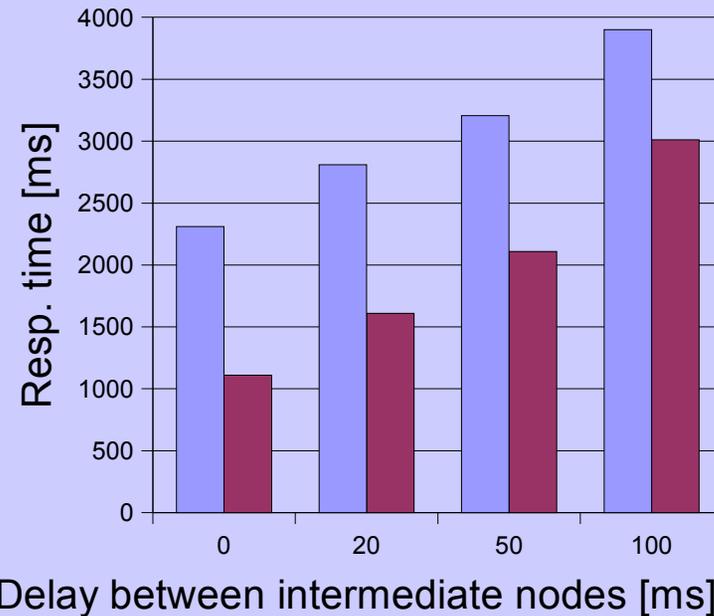

# Sensitivity to network parameters

Sensitivity to delay to origin server

Sensitivity to delay between intermediate nodes

- ◆ Two-level:

- ◆ High hit rate → less sensitive to delay to origin server

- ◆ Two steps → sensitivity to delay between edge and internal nodes

# *Conclusion*

- ◆ Two-level architecture constantly outperforms other architecture in our experiments
- ◆ Two-level architecture is sensitive to network delays between the nodes of the intermediate infrastructure
- ◆ Two level architecture is less sensitive than flat architecture to delay to origin server

# *Future work*

- ◆ Flat architecture and two-level are two extreme cases
  - ◆ Flat: every node provides every function
  - ◆ Two-level: node functions partitioned
- ◆ *In medio stat virtus*
  - ◆ Intermediate hybrid architectures are a whole new space of investigation
